SECTION I INTRODUCTION

This volume contains flow charts and analyses of all DDP-516 instructions. Separate coverage is provided for the memory reference fetch cycle. The instructions are presented in groups (i.e., load and store, arithmetic, logical, etc.). For convenient reference, the mnemonic, number of cycles, and Op Code appear on each page. Symbols and abbreviations used in the flow charts are defined in Table 1-1. A function index is provided to be used as an aid in determining function sources and definitions, (Table 1-2).

Signal Mnemonics

The electrical characteristics of the computer circuits are called: passive (+6 vdc) and active (0 vdc). The logical functions are true (logic ONE) and false (logic ZERO). In general there are two ways of relating the electrical characteristic and logical function for each signal mnemonic:

a. An assertion signal (for example, A01FF+) is logically true when it is at +6 vdc; and is logically false when it is at 0 vdc.

b. A negation signal (for example, A01FF-) is logically true when it is at 0 vdc; and is logically false when it is at +6 vdc.

A particular signal mnemonic can be labeled assertion or negation arbitrarily. The signal mnemonic convention uses the sixth character to specify assertion or negation.

SECTION II
FLOW CHARTS/INSTRUCTION ANALYSES

The instruction analyses are detailed presentations of some key signals generated within the CPU from the time an instruction operation code is recognized until the execution is complete and the next instruction's fetch cycle is initiated. The instruction fetch cycle and I-cycle are covered on pages 2-4 through 2-7. Included in an analysis are the source, destination, and operational description of the signal. The location of the logic making up the signal is also given. Within each instruction class, the definitions of Instruction Analyses are presented in alphabetical order of their mnemonic code as follows:

<u>CODE</u>	<u>INSTRUCTION</u>	<u>CODE</u>	<u>INSTRUCTION</u>
<u>Generic</u>		<u>Input-Output</u>	
ACA	Add C to A	INA	Input to A
AOA	Add ONE to A	OCP	Output Control Pulse

The flow charts summarize the sequence of events that occur within the central processor (CPU) during the execution of each instruction. The flow charts are easy to use if the reader applies the following general analysis.

With reference to the Clear A (CRA) flow chart, note that to the left of each box is an alphanumeric (such as T1) and columns of letter codes (such as R, L, S). The alphanumeric is the time during which operations within the horizontal dashed lines occur. The letter codes specify whether the functions in the same horizontal plane are levels (L), controlled by the reset clock MCRST (R), or controlled by the set clock MCSET (S).

The information within a box is in abbreviated text form, that is to say that certain key phrases have been replaced with symbology. An example is $0 \rightarrow (M)$, which means that the contents of the M-register is replaced with zeros (cleared). Another method of clearing registers used in the DDP-510 is 1's $\rightarrow (D)$. Rather than replacing the contents of the D-register with zeros, the contents are replaced with ones. This method only applies to the D-, E-, and X-registers. All other registers are cleared to all zeros.

The mnemonics to the right of the box are the signals that implement the operation described in the box. In the case of $0 \rightarrow (M)$ it is clear M-register totally on reset clock (CLMTR-) which causes the register to be cleared.

In some cases mnemonics are deliberately omitted from the flow chart for simplicity. In these cases, reference to the analyses of instructions is required.
